

MAUS Analysis User System User Guide

Chapter 1

Monte Carlo

The simulation module provides particle generation routines, GEANT4 bindings to track particles through the geometry and routines to convert modelled energy loss in detectors into digitised signals from the MICE DAQ. The Digitisation models are documented under each detector. Here we describe the beam generation and GEANT4 interface.

1.1 Beam Generation

Beam generation is handled by the MapPyBeamMaker module. Beam generation is separated into two classes. The MapPyBeamGenerator has routines to assign particles to a number of individual beam classes, each of which samples particle data from a predefined parent distribution. Beam generation is handled by the **beam** datacard.

The MapPyBeamMaker can either take particles from an external file, overwrite existing particles in the spill, add a specified number of particles from each beam definition, or sample particles from a binomial distribution. The random seed is controlled at the top level and different algorithms can be selected influencing how this is used to generate random seeds on each particle.

Each beam definition has routines for sampling from a multivariate gaussian distribution or generating ensembles of identical particles (called "pencil" beams here). Additionally it is possible to produce time distributions that are either rectangular or triangular in time to give a simplistic representation of the MICE time distribution.

The beam definition controls are split into four parts. The **reference** branch defines the centroid of the distribution; the **transverse** branch defines the transverse coordinates, x, y, px, py ; the **longitudinal** branch defines the longitudinal coordinates - time and energy/momentum and the **coupling** branch defines correlations between longitudinal and transverse. Additionally a couple of parameters are available to control random seed generation and relative weighting between different beam definitions.

In transverse, beams are typically sampled from a multivariate gaussian.

The Twiss beam ellipse is defined by

$$\mathbf{B}_\perp = m \begin{pmatrix} \epsilon_x \beta_x / p & -\epsilon_x \alpha_x & 0 & 0 \\ -\epsilon_x \alpha_x & \epsilon_x \gamma_x p & 0 & 0 \\ 0 & 0 & \epsilon_y \beta_y / p & -\epsilon_y \alpha_y \\ 0 & 0 & -\epsilon_y \alpha_y & \epsilon_y \gamma_y p \end{pmatrix} \quad (1.1)$$

The Penn beam ellipse is defined by,

$$\mathbf{B}_\perp = m \epsilon_\perp \begin{pmatrix} \beta_\perp / p & -\alpha_\perp & 0 & -\mathcal{L} + \beta_\perp B_0 / 2p \\ -\alpha_\perp & \gamma_\perp p & \mathcal{L} - \beta_\perp B_0 / 2p & 0 \\ 0 & \mathcal{L} - \beta_\perp B_0 / 2p & \beta_\perp / p & -\alpha_\perp \\ -\mathcal{L} + \beta_\perp B_0 / 2p & 0 & -\alpha_\perp & \gamma_\perp p \end{pmatrix} \quad (1.2)$$

where parameters can be controlled in datacards

1.2 GEANT4 Bindings

The GEANT4 bindings are encoded in the Simulation module. GEANT4 groups particles by run, event and track. A GEANT4 run maps to a MICE spill; a GEANT4 event maps to a single inbound particle from the beamline; and a GEANT4 track corresponds to a single particle in the experiment.

A number of classes are provided for basic initialisation of GEANT4.

- **MAUSGeant4Manager**: is responsible for handling interface to GEANT4. MAUSGeant4Manager handles initialisation of the GEANT4 bindings as well as accessors for individual GEANT4 objects (see below). Interfaces are provided to run one or many particles through the geometry, returning the relevant event data. The MAUSGeant4Manager sets and clears the event action before each run.
- **MAUSPhysicsList**: contains routines to set up the GEANT4 physical processes. Datacards settings are provided to disable stochastic processes or all processes and set a few parameters.
- **FieldPhaser**: the field phaser is a MAUS-specific tool for automatically phasing fields, for example RF cavities, such that they ramp coincidentally with incoming particles. The FieldPhaser contains routines to fire test ("reference") particles through the accelerator lattice and phase fields appropriately. The FieldPhaser phasing routines are called after GEANT4 is first initialised.
- **VirtualPlanes**: the VirtualPlanes routines are designed to extract particle data from the GEANT4 tracking independently of the GEANT4 geometry. The VirtualPlanes routines watches for steps that step across some plane in physical space, or some time, or some proper time, and then interpolates from the step ends to the plane in question.
- **FillMaterials**: (legacy) the FillMaterials routines are used to initialise a number of specific

Table 1.1: Multiple beam control parameters.

Name	Meaning
beam	dict containing beam definition parameters.
<i>The following cards should all be defined within the beam dict.</i>	
particle_generator	Set to binomial to choose the number of particles by sampling from a binomial distribution. Set to counter to choose the number of particles in each beam definition explicitly. Set to file to generate particles by reading an input file. Set to overwrite_existing to generate particles by overwriting existing primaries.
binomial_n	When using a binomial particle_generator , this controls the number of trials to make. Otherwise ignored.
binomial_p	When using a binomial particle_generator , this controls the probability a trial yields a particle. Otherwise ignored.
beam_file_format	When using a file particle_generator , set the input file format - options are <ul style="list-style-type: none"> • icool_for009 • icool_for003, • g4beamline_bl_track_file • g4mice_special_hit • g4mice_virtual_hit • mars_1 • maus_virtual_hit • maus_primary
beam_file	When using a file particle_generator , set the input file name.
file_particles_per_spill	When using a file particle_generator , this controls the number of particles per spill that will be read from the file.
random_seed	Set the random seed, which is used to generate individual random seeds for each primary (see below).
definitions	A list of dicts, each item of which is a dict defining the distribution from which to sample individual particles.

Table 1.2: Individual beam distribution parameters.

Name	Meaning
<i>The following cards should be inside a dict in the beam definitions list.</i>	
<code>random_seed_algorithm</code>	Choose from the following options <ul style="list-style-type: none"> • <code>beam_seed</code>: use the <code>random_seed</code> for all particles • <code>random</code>: use a different randomly determined seed for each particle • <code>incrementing</code>: use the <code>random_seed</code> but increment by one each time a new particle is generated • <code>incrementing_random</code>: determine a seed at random before any particles are generated; increment this by one each time a new particle is generated
<code>weight</code>	When <code>particle_generator</code> is <code>binomial</code> or <code>overwrite_existing</code> , the probability that a particle will be sampled from this distribution is given by $weight/(sum\ of\ weights)$.
<code>n_particles_per_spill</code>	When <code>particle_generator</code> is <code>counter</code> , this sets the number of particles that will be generated in each spill.
<code>reference</code>	Dict containing the reference particle definition.
<code>transverse</code>	Dict defining the longitudinal phase space distribution.
<code>longitudinal</code>	Dict defining the longitudinal phase space distribution.
<code>coupling</code>	Dict defining any correlations between transverse and longitudinal.

Table 1.3: Beam distribution reference definition.

Name	Meaning
<i>The following cards should be defined in each beam definition reference dict.</i>	
<code>position</code>	dict with elements <code>x</code> , <code>y</code> and <code>z</code> that define the reference position (mm).
<code>momentum</code>	dict with elements <code>x</code> , <code>y</code> and <code>z</code> that define the reference momentum direction. Normalised to 1 at runtime.
<code>particle_id</code>	PDG particle ID of the reference particle.
<code>energy</code>	Reference energy.
<code>time</code>	Reference time (ns).
<code>random_seed</code>	Set to 0 - this parameter is ignored.

Table 1.4: Beam definition transverse parameters.

Name	Meaning
<i>The following cards should be defined in each beam definition transverse dict.</i>	
transverse_mode	Options are <ul style="list-style-type: none"> • pencil: x, py, y, py taken from reference • penn: cylindrical beam symmetric in x and y • constant_solenoid: cylindrical beam symmetric in x and y, with beam radius calculated from on-axis B-field to give constant beam radius along a solenoid. • twiss: beam with decoupled x and y beam ellipses.
normalised_angular_momentum	if transverse_mode is penn or constant_solenoid , set \mathcal{L} .
emittance_4d	if transverse_mode is penn or constant_solenoid , set ϵ_{\perp} .
beta_4d	if transverse_mode is penn , set β_{\perp} .
alpha_4d	if transverse_mode is penn , set α_{\perp} .
bz	if transverse_mode is constant_solenoid , set the B-field used to calculate β_{\perp} and α_{\perp} .
beta_x	if transverse_mode is twiss , set β_x .
alpha_x	if transverse_mode is twiss , set α_x .
emittance_x	if transverse_mode is twiss , set ϵ_x .
beta_y	if transverse_mode is twiss , set β_y .
alpha_y	if transverse_mode is twiss , set α_y .
emittance_y	if transverse_mode is twiss , set ϵ_y .

Table 1.5: Beam definition longitudinal parameters.

Name	Meaning
<i>The following cards should be defined in each beam definition longitudinal dict.</i>	
<code>momentum_variable</code>	In all modes, set this variable to control which longitudinal variable will be used to control the input beam. Options are energy , p , pz .
<code>longitudinal_mode</code>	Options are <ul style="list-style-type: none"> • pencil: time, energy/p/pz taken from reference • gaussian: uncorrelated gaussians in time and energy/p/pz • twiss: multivariate gaussian in time and energy/p/pz • uniform_time: gaussian in energy/p/pz and uniform in time. • sawtooth_time: gaussian in energy/p/pz and sawtooth in time.
<code>beta_l</code>	In Twiss mode, set β_l
<code>alpha_l</code>	In Twiss mode, set α_l
<code>emittance_l</code>	In Twiss mode, set ϵ_l
<code>sigma_t</code>	In gaussian mode, set the RMS time.
<code>sigma_p</code>	In gaussian , uniform_time , sawtooth_time mode, set the RMS energy/p/pz.
<code>sigma_energy</code>	
<code>sigma_pz</code>	In uniform_time and sawtooth_time mode, set the start time of the parent distribution
<code>t_start</code>	
<code>t_end</code>	In uniform_time and sawtooth_time mode, set the end time of the parent distribution

Table 1.6: Beam definition coupling parameters.

Name	Meaning
<i>The following cards should be defined in each beam definition coupling dict.</i>	
<code>coupling_mode</code>	Set to none - not implemented yet.

- **MICEDetectorConstruction:** (legacy) the **MICEDetectorConstruction** routines provide an interface between the MAUS internal geometry representation encoded in **MiceModules** and **GEANT4**. **MICEDetectorConstruction** is responsible for calling the relevant routines for setting up the general engineering geometry, calling detector-specific geometry set-up routines and calling the field map set-up routines.
- **MAUSVisManager** the **MAUSVisManager** is responsible for handling interfaces with the **GEANT4** visualisation.

The **GEANT4** *Action* objects provide interfaces for MAUS-specific function calls at certain points in the tracking.

- **MAUSRunAction:** sets up the running for a particular spill. In MAUS, it just reinitialises the visualisation.
- **MAUSEventAction:** sets up the running for a particular inbound particle. At the beginning of each event, the virtual planes, tracking, detectors and stepping are all cleared. After the event the event data is pulled into the event data from each element.
- **MAUSTrackingAction:** is called when a new track is created or destroyed. If **keep_tracks** datacard is set to True, on particle creation, **MAUSTrackingAction** writes the initial and final track position and momentum to the output data tree. If **keep_steps** is set to True **MAUSTrackingAction** gets step data from **MAUSSteppingAction** and writes this also.
- **MAUSSteppingAction:** is called at each step of the particle. If **keep_steps** datacard is set to True, output step data is recorded. **MAUSSteppingAction** kills particles if they exceed the **maximum_number_of_steps** datacard. **MAUSSteppingAction** calls the **VirtualPlanes** routines on each step.
- **MAUSPrimaryGeneratorAction:** is called at the start of every event and sets the particle data for each event. In MAUS, this particle generation is handled externally and so the **MAUSPrimaryGeneratorAction** role is to look for the primary object on the Monte Carlo event and convert this into a **GEANT4** event object.
- **MAUSStackingActionKillNonMuons:** is never initialised and should be removed.

Table 1.7: Monte Carlo control parameters.

Name	Meaning
<i>General Monte Carlo controls.</i>	
<code>simulation_geometry_filename</code>	Filename for the simulation geometry - searches first in files tagged by environment variable <code>\${MICEFILES}</code> , then in the local directory.
<code>simulation_reference_particle</code>	Reference particle used for phasing fields.
<code>keep_tracks</code>	Set to boolean true to store the initial and final position/momentum of each track generated by MAUS.
<code>keep_steps</code>	Set to boolean true to store every step generated by MAUS - warning this can lead to large output files.
<code>maximum_number_of_steps</code>	Set to an integer value. Tracks taking more steps are assumed to be looping.

Table 1.8: Physics list control parameters.

<i>Physics list controls.</i>	
<code>physics_model</code>	GEANT4 physics model used to set up the physics list.
<code>physics_processes</code>	Choose which physics processes normal particles observe during tracking. Options are <ul style="list-style-type: none"> • normal particles will obey normal physics processes, scattering and energy straggling will be active. • mean_energy_loss particles will lose a deterministic amount of energy during interaction with materials and will never decay. • none Particles will never lose energy or scatter during tracking and will never decay.
<code>reference_physics_processes</code>	Choose which physics processes the reference particle observes during tracking. Options are mean_energy_loss and none . The reference particle can never have stochastic processes enabled.
<code>particle_decay</code>	Set to boolean true to enable particle decay; set to boolean false to disable.
<code>charged_pion_half_life</code>	Set the half life for charged pions.
<code>muon_half_life</code>	Set the half life for muons.
<code>production_threshold</code>	Set the geant4 production threshold.

Table 1.9: Visualisation control parameters.

<i>Visualisation controls.</i>	
<code>geant4_visualisation</code>	Set to boolean true to activate GEANT4 visualisation.
<code>visualisation_viewer</code>	Control which viewer to use to visualise GEANT4 tracks. Currently only <code>vrmlviewer</code> is compiled into GEANT4 by default. Users can recompile GEANT4 with additional viewers enabled at their own risk.
<code>visualisation_theta</code>	Set the theta angle of the camera.
<code>visualisation_phi</code>	Set the phi angle of the camera.
<code>visualisation_zoom</code>	Set the camera zoom.
<code>accumulate_tracks</code>	Not implemented.
<code>default_vis_colour</code>	Not implemented.
<code>pi_plus_vis_colour</code>	Not implemented.
<code>pi_minus_vis_colour</code>	Not implemented.
<code>mu_plus_vis_colour</code>	Not implemented.
<code>mu_minus_vis_colour</code>	Not implemented.
<code>mu_plus_vis_colour</code>	Not implemented.
<code>mu_minus_vis_colour</code>	Not implemented.
<code>e_plus_vis_colour</code>	Not implemented.
<code>e_minus_vis_colour</code>	Not implemented.
<code>gamma_vis_colour</code>	Not implemented.
<code>neutron_vis_colour</code>	Not implemented.
<code>photon_vis_colour</code>	Not implemented.
